COVID-19 critical care

TERMINOLOGY

CLINICAL CLARIFICATION

- COVID-19 (coronavirus disease 2019) is a respiratory tract infection with a newly recognized coronavirus; it spread rapidly from the point of origin in China, and was officially declared by WHO to be a pandemic on March 11, 2020.1
- Illness ranges in severity from asymptomatic or mild to severe; about 5% of diagnosed cases require critical care to manage severe manifestations and complications, including acute respiratory distress syndrome, myocardial dysfunction, and shock.2
- Most patients with severe COVID-19 seem to have a bimodal illness, where there is initial improvement before severe worsening with critical illness. This may be related to the immunologic role in the sepsis seen with COVID-19.
- Among ICU patients with COVID-19, mortality rates of 39% to 72% have been reported.2

CLASSIFICATION

- Pathogen is a betacoronavirus,3 similar to the agents of SARS (severe acute respiratory syndrome) and MERS (Middle East respiratory syndrome).3
  - Classified as a member of the species Severe acute respiratory syndrome–related coronavirus4,5
  - Designated as SARS-CoV-2 (severe acute respiratory syndrome coronavirus 2); earlier provisional name was 2019-nCoV4,5

DIAGNOSIS

CLINICAL PRESENTATION

- History
  - In symptomatic patients, illness may evolve over the course of a week or longer, beginning with mild symptoms; syndrome is usually dominated by respiratory complaints, but it may include alterations in taste and smell, gastrointestinal symptoms, myalgias, and fatigue (often profound).6
    - Median time from symptom onset to pneumonia is 5 days; time to severe hypoxemia is 7 to 12 days.7
  - In patients with progression to severe disease, deterioration is typically rapid and characterized by progressive hypoxemia which may or may not be associated with symptoms of dyspnea.8
  - Cardiac, vascular, and neurologic manifestations may accompany pulmonary disease, resulting in localized symptoms (eg, pain, including headache) and alterations in cognition and level of consciousness.
- Physical examination
  - Reported case series have not fully detailed physical findings, but clinicians should be particularly attuned to pulmonary and hemodynamic indicators of critical illness.
    - Patients in apparent distress require immediate assessment of airway, breathing, and circulation (eg, pulses, blood pressure).
    - Oxygenation should be assessed promptly by peripheral saturation (eg, pulse oximetry).9
  - Fever is typical, often exceeding 39 °C. Patients in the extremes of age or with immunodeficiency may not develop fever.6
  - Patients with severe disease may appear quite ill, with tachypnea and labored respirations.
  - Tachyarrhythmias may be noted on auscultation or cardiac monitor.10
  - Signs of arterial or deep venous thrombosis may be detected.
    - Large-vessel stroke and associated neurologic deficit has been described as the presenting clinical event.11
  - Other reported neurologic findings in severe disease include hyperactive deep tendon reflexes, ankle clonus, and positive Babinski sign.12
  - Patients may be agitated, confused, or poorly responsive.12
  - A variety of skin changes have been described, including purpura13 and petechiae14 as well as the vesicular15 and nonspecific erythematous exanthems16 typical of viral infections. Typical viral eruptions generally occur early in the disease, but remnants may be apparent in patients presenting with severe disease.
  - Hypotension, tachycardia, and cool/clammy extremities suggest shock.
    - In children, hypotension plus 2 or more of the following criteria:9
      - Altered mental status
      - Tachycardia (heart rate more than 160 beats per minute in infants or 150 in older children) or bradycardia (heart rate less than 90 in infants or 70 in older children)
      - Prolonged capillary refill (more than 2 seconds) or warm vasodilation and bounding pulses
      - Tachypnea
      - Mottled skin, petechiae, or purpura
      - Oliguria
      - Hyperthermia or hypothermia

CAUSES AND RISK FACTORS

- **Causes**
  - Infection due to SARS-CoV-2 (2019 novel coronavirus)
  - Person-to-person transmission has been documented and is presumed to occur by close contact, probably via respiratory droplets.
  - Additional means of transmission are possible but not established (eg, contact with infected environmental surfaces, fomites, fecal-oral route).

- **Risk factors and/or associations**
  - Age
    - Risk of severe disease increases with age; severe illness is rare in children and adolescents.
      - In data from China, case fatality rates were 14.8% for patients aged 80 years or older, 8% for those aged 70 to 79 years, and 3.6% for those aged 60 to 69 years.
      - In data from the United States, case fatality rates were 10% to 27% among patients aged 85 years or older, 3% to 11% for those aged 65 to 84 years, and 1% to 3% for those aged 55 to 64 years.
  - Sex
    - Male sex may be a risk factor for severe disease; in a series of 5700 hospitalized patients with COVID-19, 60.3% were male; among ICU patients, 66.5% were male.
  - Other risk factors/associations
    - Various comorbidities (especially if not well controlled) have been associated with more severe disease.
      - Heart disease
      - Hypertension
      - Previous stroke
      - Diabetes
      - Chronic lung disease, including moderate or severe asthma
      - Chronic liver or kidney disease
      - Immunocompromise
      - BMI of 40 or more

DIAGNOSTIC PROCEDURES

- **Primary diagnostic tools**
  - Polymerase chain reaction tests are the standard for diagnosis. Specific methods and availability vary; public health authorities may assist in arranging diagnostic testing in some areas. Attempts to culture the virus are not recommended.
  - WHO and CDC have slightly different criteria for whom to test, and the rapid evolution of the pandemic and variable availability of testing render actual practice very fluid. Both organizations support testing in hospitalized patients with a clinically compatible illness.
  - Collection of specimens from upper respiratory tract or lower respiratory tract is recommended for polymerase chain reaction testing. Care must be taken to minimize risks associated with aerosolization during specimen collection.
  - CDC provides specific instructions for collection and handling of specimens submitted for testing at CDC laboratories (commercial and institutional laboratories and public health laboratories in other jurisdictions may have different requirements).
  - **Upper respiratory tract**
    - Nasopharyngeal, deep nasal (midturbinate), anterior nare, or oropharyngeal swab may be submitted. Only synthetic fiber (eg, polyester) swabs with plastic or wire shafts are acceptable. Flocked swabs are recommended for obtaining deep nasal specimens. If more than one swab is collected, they may be placed in the same container.
    - For nasopharyngeal specimen, insert swab into nostril parallel to palate. Leave swab in place for a few seconds to absorb secretions.
    - For deep nasal specimen, insert a flocked swab about 2 cm and rotate; repeat on opposite side, using the same swab.
    - For anterior nares, insert a flocked swab about 1 cm, rotate in contact with mucus membrane, and leave in place for 10 to 15 seconds; repeat on opposite side, using same swab.
    - For oropharyngeal specimen, swab the posterior pharynx, avoiding tongue and tonsils.
    - Nasopharyngeal wash (or aspirate) or nasal aspirate specimens (using 1 to 1.5 mL nonbacteriostatic saline) are also acceptable in some cases.
    - Because testing methods vary, it is advisable to check with the laboratory to determine which specimens are suitable for the available test.
  - **Lower respiratory tract**
    - Bronchoalveolar lavage or tracheal aspirate are suitable lower respiratory tract specimens.
A deep cough sputum specimen (collected after mouth rinse) is also acceptable. WHO and CDC advise against attempts to induce sputum, because the process may increase aerosolization and risk of transmission.

- Infectious Diseases Society of America guidelines provide additional guidance and an algorithm, including indications for repeated testing when suspicion for disease is high but initial test result is negative.
- Favor nasopharyngeal, nasal, or midturbinate specimens over oropharyngeal or salivary specimens for initial testing.
- For patients with high likelihood of disease but negative initial result, repeated testing is recommended; in patients with lower respiratory tract symptoms, sputum or other lower respiratory tract specimen is recommended for repeated testing.

- Other testing should be performed concurrently, if indicated, to identify alternative pathogens (eg, influenza, respiratory syncytial, and other viruses; bacterial pathogens); such tests should not delay arrangements for SARS-CoV-2 polymerase chain reaction testing.

- Coinfections have been reported, but the frequency is unknown.

- In patients with moderate to severe disease, chest imaging is essential to document extent and severity of lung involvement and to serve as a baseline against which to compare should respiratory status worsen; plain radiography, CT, and ultrasonography have been used.

- Recommendations for COVID-19-specific diagnostic use differ regionally, according to availability of testing, prevalence of disease, and public policy.
- During the peak of the outbreak in Wuhan, China, CT scan was considered a surrogate diagnostic modality, based on the following factors: greater sensitivity compared with chest radiographs; the observation that CT may find characteristic abnormalities even in the absence of a positive molecular test result; the high prevalence of COVID-19 in that geographic area; and the public health goal of detecting and isolating all infected persons.
- CDC recommends against using chest radiograph or CT as a specific diagnostic measure for COVID-19; American College of Radiology cautions that findings are not specific to that disease and overlap with other viral pneumonias.

- In patients with severe disease, CT may offer an advantage over plain radiographs in distinguishing progression of infection from heart failure due to myocarditis or from pulmonary embolism (both commonly associated with COVID-19).

- Routine blood work should be ordered initially and repeated as appropriate for clinical management based on disease severity (eg, CBC, coagulation studies, chemistry panel including tests of hepatic and renal function and—if sepsis is suspected—lactate level and blood cultures). Troponin and B-type natriuretic peptide levels may be helpful in assessing the possibility of myocardial involvement.

- Clinicians should report suspected cases of COVID-19 to appropriate public health authorities, who can facilitate testing if necessary and can undertake contact tracing and monitoring. In the United States, contact local or state health department.

- Laboratory

  - Positive identification of SARS-CoV-2 RNA by a polymerase chain reaction test is considered confirmation of diagnosis.
  - Sensitivity of these tests is unknown, but false-negative results have been reported; repeated sampling should be considered if suspicion for COVID-19 is high and initial result is negative; in patients with severe pulmonary involvement, lower respiratory tract specimens may provide a higher yield.

  - Routine blood work is not diagnostic, but a pattern of typical abnormalities has emerged, particularly in patients with severe illness:
    - Leukopenia may be observed and relative lymphopenia is common, especially in patients with more severe illness.
    - Anemia was noted in about half of patients in one series.
    - Both elevated and low platelet counts have been seen.
    - Prolonged prothrombin time has been reported.
    - Levels of D-dimer and fibrinogen may be elevated.
    - Elevated levels of lactate dehydrogenase and liver enzymes (ALT and AST) are common.
    - Serum procalcitonin levels are usually within reference range; elevated levels have been seen in patients with secondary infection.
    - Serum levels of some other acute phase reactants (eg, C-reactive protein, ferritin) are elevated in most patients, as is the erythrocyte sedimentation rate.
COVID-19 critical care

Troponin level is commonly elevated, but it does not necessarily signify myocardial infarction in the absence of other indicators (eg, ECG changes); similarly, B-type natriuretic peptide level may be elevated without necessarily indicating presence of heart failure.

Some experts caution against measuring these biomarkers in the absence of suggestive clinical findings, whereas others note the possibility that elevations suggest noncoronary myocardial involvement that may benefit from early use of vasopressors and inotropes.

- Lactate level of 2 mmol/L or higher suggests presence of septic shock.

Imaging

- Chest imaging (eg, plain radiography, CT, ultrasonography) has shown abnormalities in most reported patients; it usually shows bilateral involvement, varying from consolidation in more severely ill patients to ground-glass opacities in less severe and recovering pneumonia.
- CT appears to be more sensitive than plain radiographs, but normal appearance on CT does not preclude the possibility of COVID-19.
- Bedside ultrasonography is widely used to monitor progression of pulmonary infiltrates, and to assess cardiac function and fluid status; it may also be used to detect deep vein or vascular catheter thrombosis, which appear to be common in patients with COVID-19.

DIFFERENTIAL DIAGNOSIS

Most common

- Influenza
  - Presentation includes fever, coryza, sore throat, dry cough, and myalgias; unlike COVID-19, influenza usually has a fairly sudden onset.
  - Most cases are self-limited, but elderly persons or those with significant comorbidities often require hospitalization.
  - Usually occurs in winter months in temperate climates but is less seasonal in equatorial regions.
  - Patients with severe disease may have abnormal chest radiographic findings suggesting influenzal pneumonia or secondary bacterial pneumonia.
  - Positive result on rapid influenza diagnostic test confirms influenza diagnosis with high specificity during typical season; negative result does not rule out influenza.

- Other viral pneumonias
  - Presentations include fever, dry cough, and dyspnea.
  - Physical examination may find scattered rales.
  - Chest radiography usually shows diffuse patchy infiltrates.
  - Diagnosis is usually clinical. Testing for specific viral causes may be done; multiplex panels can test simultaneously for a number of common viral respiratory pathogens such as respiratory syncytial virus, adenovirus, and others.

- Bacterial pneumonia
  - Presentation includes fever, cough, and dyspnea; pleuritic pain occurs in some cases.
  - Physical examination may find signs of consolidation (eg, dullness to percussion, auscultatory rales, tubular breath sounds).
  - Chest radiography usually shows lobar consolidation or localized patchy infiltrate.
  - Sputum examination may find abundant polymorphonuclear leukocytes and a predominant bacterial organism.
  - Pneumococcal or legionella antigens may be detectable in urine; sputum culture may find those or other pathogens.

TREATMENT

GOALS

- Ensure adequate oxygenation and hemodynamic support during acute phase of illness.
- Prevent complications where possible (eg, thromboses); monitor for and treat unavoidable complications (eg, myocardial dysfunction).

DISPOSITION

Admission criteria

- WHO provides criteria for severe pneumonia.
  - Severe pneumonia characterized by tachypnea (respiratory rate greater than 30 breaths per minute), severe respiratory distress, inadequate oxygenation (eg, SpO₂ of 93% or less).
  - Pediatric criteria include central cyanosis or SpO₂ less than 90%; signs of severe respiratory distress (eg, grunting, chest retractions); inability to drink or breastfeed; lethargy, altered level of consciousness, seizures; severe tachypnea defined by age:
    - Younger than 2 months: 60 or more breaths per minute.
    - Aged 2 to 11 months: 50 or more breaths per minute.

At present, no specific therapeutic agent is approved for treatment of this infection. Several existing drugs are being used under clinical trial and compassionate use protocols based on in vitro activity (against this or related viruses) and on limited clinical experience. Distress syndrome have been modified, and many institutions have created their own protocols to have unique characteristics. Existing published guidelines for management of sepsis and acute respiratory distress syndrome have been modified, and many institutions have created their own protocols.

### Treatment Options

- **Standard, contact, and (at least) droplet precautions should be implemented as soon as the diagnosis is suspected:** Airborne precautions are recommended if resources allow, especially for aerosol-generating procedures.
- **Immediately provide the patient with a face mask (or, if supplies are critically low, at least a cloth face cover) to reduce droplet spread and place the patient in a closed room, ideally one with structural and engineering safeguards against airborne transmission (eg, negative pressure, frequent air exchange).**
- **The pace of the pandemic and the severity of illness have necessitated urgent response but have limited the development of evidence-based critical care guidelines specific to this infection, which some experienced clinicians consider to have unique characteristics. Existing published guidelines for management of sepsis and acute respiratory distress syndrome have been modified, and many institutions have created their own protocols.**
- **At present, no specific therapeutic agent is approved for treatment of this infection. Several existing drugs are being used under clinical trial and compassionate use protocols based on in vitro activity (against this or related viruses) and on limited clinical experience. Chloroquine and hydroxychloroquine have been used in China and South Korea, reportedly with favorable results, although details are lacking. Initial promise led to an emergency use authorization by FDA in the United States. Subsequent studies have failed to show a significant benefit, but they have highlighted the risk of QT prolongation and cardiac arrhythmias.**
- **Azithromycin has been used in combination with hydroxychloroquine in some protocols; however, azithromycin is also associated with cardiac arrhythmias, and the possible increased risk posed by the combination must be considered.**
- **In the United States, emergency use authorization for chloroquine and hydroxychloroquine has been issued by FDA to permit use in hospitalized adult and adolescent patients for whom a clinical trial is not available or feasible. Surviving Sepsis Campaign guideline on managing critically ill adults with COVID-19 states that data are insufficient to permit use in hospitalized adult and adolescent patients for whom a clinical trial is not available or feasible.**
- **In patients admitted to hospital with COVID-19, Infectious Diseases Society of America recommends hydroxychloroquine or chloroquine in the context of a clinical trial, and in combination with azithromycin only in the context of a clinical trial, based on evidence of very low certainty.**
- **NIH guidelines do not recommend for or against chloroquine or hydroxychloroquine because of insufficient data; they recommend against high-dose chloroquine (600 mg twice daily for 10 days) and against the addition of azithromycin to hydroxychloroquine. The guidelines note that when chloroquine or hydroxychloroquine is used, patients must be monitored for adverse effects, particularly prolonged QTc interval.**
- **A large observational study published after the aforementioned guidelines reported data on patients with COVID-19 of whom 58.9% received hydroxychloroquine with or without azithromycin. The authors concluded that hydroxychloroquine was not associated with a significantly higher or lower risk of intubation or death and noted the need for an adequately powered randomized controlled trial.**
- **A large retrospective study found no significant differences in in-hospital mortality between patients who received hydroxychloroquine plus azithromycin, either drug alone, or neither drug.**
Lopinavir-ritonavir is FDA-approved for treatment of HIV infection. It has been used in China in conjunction with interferon alfa for treatment of some patients with COVID-19, but reported results have been disappointing.

- A trial in 199 patients with COVID-19 comparing lopinavir-ritonavir with standard care did not show a significant difference in time to improvement or in mortality at 28 days, nor were there differences in duration of viral RNA in oropharyngeal specimens.

- Surviving Sepsis Campaign guideline on managing critically ill adults with COVID-19 recommends against use of recombinant interferons, based on lack of data in COVID-19 and on data from studies on MERS showing lack of efficacy.

- In patients admitted to hospital with COVID-19, Infectious Diseases Society of America recommends lopinavir-ritonavir only in the context of a clinical trial.

Immunomodulators are also being investigated for mitigation of cytokine release syndrome believed to be a factor in severe acute respiratory distress syndrome and shock in COVID-19 (e.g., tocilizumab and sarilumab are both monoclonal antibodies against interleukin-6 receptor).

- Surviving Sepsis Campaign guideline on managing critically ill adults with COVID-19 states that data are insufficient to make a recommendation on the use tocilizumab; the guideline did not evaluate other monoclonal antibodies.

- In patients admitted to hospital with COVID-19, Infectious Diseases Society of America recommends tocilizumab only in the context of a clinical trial, based on evidence of very low certainty.

- NIH COVID-19 treatment guideline states that data are insufficient to recommend for or against use of these agents.

Studies on the therapeutic efficacy of convalescent plasma are underway in various countries. In the United States, authorization must be obtained through FDA.

- Surviving Sepsis Campaign guideline on managing critically ill adults with COVID-19 suggests that convalescent plasma not be used on the basis of data in other viral infections, lack of data in COVID-19, and uncertainties about safety.

- In patients admitted to hospital with COVID-19, Infectious Diseases Society of America recommends convalescent plasma in the context of a clinical trial, based on evidence of very low certainty.

- NIH COVID-19 treatment guideline states that data are insufficient to recommend for or against use of convalescent plasma or hyperimmune immunoglobulin. It recommends against the use of non-SARS-CoV-2 IV immunoglobulin except in a clinical trial or unless there is another indication for it.

Information on therapeutic trials and expanded access is available at ClinicalTrials.gov.

- Corticosteroid therapy is not recommended for viral pneumonia but is suggested by some authorities for patients with COVID-19 who have refractory shock or acute respiratory distress syndrome.

- Surviving Sepsis Campaign guideline on managing critically ill adults with COVID-19 supports using corticosteroids in mechanically ventilated patients with COVID-19 and acute respiratory distress syndrome (but not those with respiratory failure in the absence of that syndrome) and in patients with COVID-19 and refractory shock; short-course, low-dose regimens are preferred.

- Similarly, Infectious Diseases Society of America suggests against the use of corticosteroids in hospitalized patients with COVID-19 and pneumonia, but it recommends their use in the context of a clinical trial for patients with COVID-19 and acute respiratory distress syndrome.

- NIH COVID-19 treatment guideline recommends against routine use in mechanically ventilated patients without acute respiratory distress syndrome, notes insufficient data to recommend for or against it in mechanically ventilated patients with that syndrome, and recommends low-dose corticosteroids in patients with refractory shock.

- FDA is investigating a controversy that has arisen regarding the use of NSAIDs in patients with COVID-19; however, there is no published evidence connecting the use of NSAIDs with worsening COVID-19 symptoms.

- NIH COVID-19 treatment guideline recommends that use of acetaminophen and NSAIDs in patients with COVID-19 should not differ from that in patients without COVID-19.

- Until a diagnosis of COVID-19 is confirmed by polymerase chain reaction test, appropriate antimicrobial therapy for other viral pathogens (e.g., influenza virus) or bacterial pathogens should be administered in accordance with the site of acquisition (hospital or community), epidemiologic risk factors, and local antimicrobial susceptibility patterns.

- Additionally, Surviving Sepsis Campaign guideline on managing critically ill adults with COVID-19 supports use of empiric antimicrobial therapy in mechanically ventilated patients with COVID-19 and respiratory failure, with daily consideration for de-escalation.

- NIH COVID-19 treatment guideline considers broad-spectrum antimicrobial therapy to be standard for patients in shock.
Based on concerns about the possible role of micro- and macrovascular thrombosis in the pathophysiology of this disease, the use of anticoagulation is being studied. At present, in the absence of a standard indication for it, published guidelines do not recommend therapeutic anticoagulation but do recommend use of prophylactic regimens in any hospitalized patient with COVID-19.\textsuperscript{34, 63, 48}

Otherwise, treatment is largely supportive and includes oxygen supplementation and conservative fluid support; usual measures to prevent common complications (eg, pressure injury, stress ulceration, secondary infection) are applicable.\textsuperscript{9}

Management of shock includes use of vasopressors if fluid administration does not restore adequate perfusion. Surviving Sepsis Campaign,\textsuperscript{52} NIH COVID-19 treatment guideline,\textsuperscript{48} and WHO\textsuperscript{9} provide guidance specific to the treatment of shock in patients with COVID-19.

- In adults, begin with norepinephrine; epinephrine or vasopressin is preferred as second line over dopamine if norepinephrine is unavailable
  - Hemodynamic goal: mean arterial pressure of 60 to 65 mm Hg\textsuperscript{52}
- In patients who do not respond adequately to usual doses of norepinephrine, Surviving Sepsis Campaign guideline on managing critically ill adults with COVID-19 recommends adding vasopressin rather than further titrating norepinephrine.\textsuperscript{52}
- For patients with COVID-19, refractory shock despite fluid and norepinephrine, and evidence of cardiac dysfunction, Surviving Sepsis Campaign guideline on managing critically ill adults with COVID-19 recommends adding dobutamine rather than further titrating norepinephrine.\textsuperscript{52}
- In children, epinephrine is considered the first line agent, and norepinephrine may be added if necessary.\textsuperscript{9}

Drug therapy

- Antiviral agent
  - Remdesivir\textsuperscript{64}
    - Remdesivir Solution for injection; Neonates weighing 3.5 kg or more requiring invasive mechanical ventilation and/or extracorporeal membrane oxygenation (ECMO): The NIH COVID-19 treatment guidelines recommend remdesivir for hospitalized patients with severe COVID-19. 5 mg/kg/dose IV once on day 1 then 2.5 mg/kg/dose IV once daily for 9 days suggested by FDA EUA statement.
    - Remdesivir Solution for injection; Neonates weighing 3.5 kg or more NOT requiring invasive mechanical ventilation and/or extracorporeal membrane oxygenation (ECMO): The NIH COVID-19 treatment guidelines recommend remdesivir for hospitalized patients with severe COVID-19. 5 mg/kg/dose IV once on day 1 then 2.5 mg/kg/dose IV once daily for 4 days suggested by FDA EUA statement. May extend treatment for up to 5 additional days if no clinical improvement.
    - Remdesivir Solution for injection; Infants, Children, and Adolescents weighing 3.5 to 39 kg requiring invasive mechanical ventilation and/or extracorporeal membrane oxygenation (ECMO): The NIH COVID-19 treatment guidelines recommend remdesivir for hospitalized patients with severe COVID-19. 5 mg/kg/dose IV once on day 1 then 2.5 mg/kg/dose IV once daily for 9 days suggested by FDA EUA statement.
    - Remdesivir Solution for injection; Infants, Children, and Adolescents weighing 3.5 to 39 kg NOT requiring invasive mechanical ventilation and/or extracorporeal membrane oxygenation (ECMO): The NIH COVID-19 treatment guidelines recommend remdesivir for hospitalized patients with severe COVID-19. 5 mg/kg/dose IV once on day 1 then 2.5 mg/kg/dose IV once daily for 4 days suggested by FDA EUA statement. May extend treatment for up to 5 additional days if no clinical improvement.
    - Remdesivir Solution for injection; Children and Adolescents weighing 40 kg or more requiring invasive mechanical ventilation and/or extracorporeal membrane oxygenation (ECMO): The NIH COVID-19 treatment guidelines recommend remdesivir for hospitalized patients with severe COVID-19. 200 mg IV once on day 1 then 100 mg IV once daily for 9 days suggested by FDA EUA statement.
    - Remdesivir Solution for injection; Children and Adolescents weighing 40 kg or more NOT requiring invasive mechanical ventilation and/or extracorporeal membrane oxygenation (ECMO): The NIH COVID-19 treatment guidelines recommend remdesivir for hospitalized patients with severe COVID-19. 200 mg IV once on day 1 then 100 mg IV once daily for 4 days suggested by FDA EUA statement. May extend treatment for up to 5 additional days if no clinical improvement.
    - Remdesivir Solution for injection; Adults requiring invasive mechanical ventilation and/or extracorporeal membrane oxygenation (ECMO): The NIH COVID-19 treatment guidelines recommend remdesivir for hospitalized patients with severe COVID-19. 200 mg IV once on day 1 then 100 mg IV once daily for 9 days suggested by FDA EUA statement.
    - Remdesivir Solution for injection; Adults NOT requiring invasive mechanical ventilation and/or extracorporeal membrane oxygenation (ECMO): The NIH COVID-19 treatment guidelines recommend remdesivir for hospitalized patients with severe COVID-19. 200 mg IV once on day 1 then 100 mg IV once daily for 4 days suggested by FDA EUA statement. May extend treatment for up to 5 additional days if no clinical improvement.
Antimalarial agents
  - Chloroquine
    - Chloroquine Phosphate Oral tablet; Adolescents weighing 50 kg or more: Data are limited; efficacy has not been established. Due to a lack of clinical data, the NIH COVID-19 treatment guidelines do not give recommendations for or against the use of chloroquine; however, if used, guidelines advise monitoring for adverse events including QT interval prolongation. 1,000 mg (600 mg base) PO on day 1 then 500 mg (300 mg base) PO once daily for 4 to 7 days suggested by FDA EUA statement. NIH recommends against the use of high-dose, twice daily chloroquine.
    - Chloroquine Phosphate Oral tablet; Adults weighing 50 kg or more: Data are limited; efficacy has not been established. Due to a lack of clinical data, the NIH COVID-19 treatment guidelines do not give recommendations for or against the use of chloroquine; however, if used, guidelines advise monitoring for adverse events including QT interval prolongation. 1,000 mg (600 mg base) PO on day 1 then 500 mg (300 mg base) PO once daily for 4 to 7 days suggested by FDA EUA statement. NIH recommends against the use of high-dose, twice daily chloroquine.
  - Hydroxychloroquine
    - Hydroxychloroquine Sulfate Oral tablet; Infants and Children: Efficacy and optimal dosing not established. Due to a lack of clinical data, the NIH COVID-19 treatment guidelines do not give recommendations for or against the use of hydroxychloroquine; however, if used, guidelines advise monitoring for adverse events, including QT interval prolongation. Based on extrapolation from pediatric dosing for other indications and comparative doses to adult dosing regimens suggested for COVID-19, doses of 6.5 mg (5 mg base)/kg/dose PO every 12 hours [Max: 400 mg/dose (310 mg base/dose)] for 2 doses, then 3.25 mg (2.5 mg base)/kg/dose every 12 hours [Max: 200 mg/dose (155 mg base/dose)] are being used in limited pediatric dosing protocols; a 5- to 20-day course is being used in adult patients.
    - Hydroxychloroquine Sulfate Oral tablet; Adolescents weighing less than 50 kg: Efficacy and optimal dosing not established. Due to a lack of clinical data, the NIH COVID-19 treatment guidelines do not give recommendations for or against the use of hydroxychloroquine; however, if used, guidelines advise monitoring for adverse events, including QT interval prolongation. Based on extrapolation from pediatric dosing for other indications and comparative doses to adult dosing regimens suggested for COVID-19, doses of 6.5 mg (5 mg base)/kg/dose PO every 12 hours [Max: 400 mg/dose (310 mg base/dose)] for 2 doses, then 3.25 mg (2.5 mg base)/kg/dose every 12 hours [Max: 200 mg/dose (155 mg base/dose)] are being used in limited pediatric dosing protocols; a 5- to 20-day course is being used in adult patients.
    - Hydroxychloroquine Sulfate Oral tablet; Adolescents weighing 50 kg or more: Data are limited and inconclusive. Due to a lack of clinical data, the NIH COVID-19 treatment guidelines do not give recommendations for or against the use of hydroxychloroquine; however, if used, guidelines advise monitoring for adverse events, including QT interval prolongation. Dosing regimens, alone and in combination, are being evaluated, including 400 mg (310 mg base) PO twice daily on day 1 then 200 mg (155 mg base) PO twice daily for 4 days; 200 mg (155 mg base) PO twice daily for 5 to 20 days; 200 mg (155 mg base) PO 3 times daily for 10 days; 1,200 mg (930 mg base) PO twice daily for 4 days; 200 mg (155 mg base) PO twice daily for 5 to 20 days; 200 mg (155 mg base) PO 3 times daily for 10 days; 1,200 mg (930 mg base) PO twice daily for 3 days followed by 800 mg (620 mg base) PO daily for 2 to 3 weeks; and 600 mg (465 mg base) PO twice daily on day 1 then 400 mg (310 mg base) PO daily for 4 days. Additional clinical evaluation is needed.
    - Hydroxychloroquine Sulfate Oral tablet; Adults weighing less than 50 kg: Data are limited; efficacy has not been established. Due to a lack of clinical data, the NIH COVID-19 treatment guidelines do not give recommendations for or against the use of hydroxychloroquine; however, if used, guidelines advise monitoring for adverse events, including QT interval prolongation. Due to the potential for toxicities, they recommend against the use of azithromycin with hydroxychloroquine outside of clinical trials. 800 mg (620 mg base) PO on day 1 then 400 mg (310 mg base) PO daily for 4 to 7 days suggested by FDA EUA statement. NIH recommends against the use of high-dose, twice daily chloroquine.
    - Hydroxychloroquine Sulfate Oral tablet; Adults weighing 50 kg or more: Data are limited; efficacy has not been established. Due to a lack of clinical data, the NIH COVID-19 treatment guidelines do not give recommendations for or against the use of chloroquine; however, if used, guidelines advise monitoring for adverse events including QT interval prolongation. 1,000 mg (600 mg base) PO on day 1 then 500 mg (300 mg base) PO once daily for 4 to 7 days suggested by FDA EUA statement. NIH recommends against the use of high-dose, twice daily chloroquine.
COVID-19 critical care

- **Monoclonal antibodies**
  - **Tocilizumab**
    - Tocilizumab Solution for injection; Adults: Available data are limited, and efficacy has not been established. Due to a lack of clinical data, the NIH COVID-19 treatment guidelines do not recommend for or against the use of IL-6 receptor inhibitors, such as tocilizumab. 4 to 8 mg/kg/dose (Usual dose: 400 mg; Max dose: 800 mg) IV once is being evaluated in combination with antiviral therapy. A second dose 8 to 12 hours after the first infusion may be considered. One protocol suggests a possible third dose 16 to 24 hours after the first dose.
  - **Sarilumab**
    - **Intravenous dosage**
      - Sarilumab Solution for injection; Adults: Efficacy has not been established. Due to a lack of clinical data, the NIH COVID-19 treatment guidelines do not give recommendations for or against the use of IL-6 receptor inhibitors, such as sarilumab. 400 mg IV once in combination with antiviral therapy.
    - **Subcutaneous dosage**
      - Sarilumab Solution for injection; Adults: Efficacy has not been established. Due to a lack of clinical data, the NIH COVID-19 treatment guidelines do not give recommendations for or against the use of IL-6 receptor inhibitors, such as sarilumab. 200 or 400 mg subcutaneously once in combination with antiviral therapy.

- **Vasopressors**
  - **Norepinephrine**
    - Norepinephrine Bitartrate Solution for injection; Neonates†: 0.1 to 0.5 mcg/kg/minute continuous IV infusion; titrate every 30 minutes to clinical response (Usual Max: 2 mcg/kg/minute).
    - Norepinephrine Bitartrate Solution for injection; Infants†, Children†, and Adolescents†: 0.1 mcg/kg/minute continuous IV infusion; titrate to clinical response (Usual Max: 2 mcg/kg/minute).
    - Norepinephrine Bitartrate Solution for injection; Adults: 0.1 mcg/kg/minute (weight-based) or 8 to 12 mcg/minute (flat-dose) continuous IV infusion, initially. Titrated by 0.02 mcg/kg/minute (or more in emergency cases) to clinical response. Usual dosage range: 0.05 to 0.4 mcg/kg/minute (weight-based) or 2 to 4 mcg/minute (flat-dose). Infusion rates up to 3.3 mcg/kg/minute have been used.
  - **Epinephrine**
    - Epinephrine Hydrochloride Solution for injection; Infants†, Children†, and Adolescents†: 0.1 to 1 mcg/kg/minute continuous IV infusion; titrate to clinical response. Doses up to 5 mcg/kg/minute may be necessary.
    - Epinephrine Hydrochloride Solution for injection; Adults: 0.05 to 2 mcg/kg/minute continuous IV infusion; titrate by 0.05 to 0.2 mcg/kg/minute every 10 to 15 minutes to clinical response.
  - **Vasopressin**
    - Vasopressin Solution for injection; Adults: 0.01 unit/minute continuous IV infusion; titrate by 0.005 unit/minute every 10 to 15 minutes to clinical response. Max: 0.07 unit/minute.

- **Inotrope**
  - **Dobutamine**
    - Dobutamine Hydrochloride Solution for injection; Adults: 0.5 to 1 mcg/kg/minute continuous IV infusion; titrate to clinical response. Usual dosage range: 2 to 20 mcg/kg/minute. Max: 40 mcg/kg/minute.

- **Corticosteroid**
  - **Hydrocortisone**
    - Hydrocortisone Sodium Succinate Solution for injection; Neonates: 1 mg/kg/dose IV every 8 to 12 hours for 1 to 5 days.
    - Hydrocortisone Sodium Succinate Solution for injection; Infants and Children 1 month to 2 years: 2 mg/kg [weight-based], 25 mcg [flat-dose], or 100 mg/m2 [BSA-based] IV bolus, followed by 1 to 2 mg/kg/day [weight-based] or 50 to 100 mg/m2/day [BSA-based] IV in divided doses at 6-hour intervals or as a continuous IV infusion.
    - Hydrocortisone Sodium Succinate Solution for injection; Children 3 to 12 years: 2 mg/kg (Max: 100 mg) [weight-based], 50 mcg [flat-dose], or 100 mg/m2 [BSA-based] IV bolus, followed by 1 to 2 mg/kg/day [weight-based] or 50 to 100 mg/m2/day [BSA-based] IV in divided doses at 6-hour intervals or as a continuous IV infusion.
    - Hydrocortisone Sodium Succinate Solution for injection; Adolescents: 2 mg/kg (Max: 100 mg) [weight-based], 100 mg [flat-dose], or 100 mg/m2 [BSA-based] IV bolus, followed by 1 to 2 mg/kg/day [weight-based] or 50 to 100 mg/m2/day [BSA-based] IV in divided doses at 6-hour intervals or as a continuous IV infusion.
    - Hydrocortisone Sodium Succinate Solution for injection; Adults: 50 mg IV every 6 hours or 200 mg/day continuous IV infusion. Taper dose once vasopressors are no longer required.

- **Anticoagulants**
  - **Enoxaparin**
    - Enoxaparin Sodium (Porcine) Solution for injection; Neonates and Infants younger than 2 months†: 0.75 mg/kg subcutaneously every 12 hours; adjust dose to maintain an anti-factor Xa concentration of 0.1 to 0.3 International Units/mL.
- **Rocuronium Bromide Solution for injection; Neonates**: 0.45 to 0.6 mg/kg IV once, followed by 0.075 to 0.6 mg/kg/dose IV as needed; adjust dose and interval to patient’s twitch response. Coadministration of certain drugs may need to be avoided or dosage adjustments may be necessary; review drug interactions.

- **Rocuronium Bromide Solution for injection; Infants, Children, and Adolescents**: 0.45 to 0.6 mg/kg IV once, followed by 0.075 to 0.6 mg/kg/dose IV as needed; adjust dose and interval to patient’s twitch response. Coadministration of certain drugs may need to be avoided or dosage adjustments may be necessary; review drug interactions.

- **Rocuronium Bromide Solution for injection; Adults**: 0.6 to 1 mg/kg IV once, followed by 0.1 to 1 mg/kg/dose IV as needed; adjust dose and interval to patient’s twitch response. Coadministration of certain drugs may need to be avoided or dosage adjustments may be necessary; review drug interactions.

- **Continuous infusion intravenous dosage**
  - **Rocuronium Bromide Solution for injection; Neonates**: 0.6 mg/kg IV bolus, followed by 5 to 10 mcg/kg/minute continuous IV infusion; titrate to patient’s twitch response. Coadministration of certain drugs may need to be avoided or dosage adjustments may be necessary; review drug interactions.
  - **Rocuronium Bromide Solution for injection; Infants, Children, and Adolescents**: 0.6 mg/kg IV bolus, followed by 5 to 10 mcg/kg/minute continuous IV infusion; titrate to patient’s twitch response. Coadministration of certain drugs may need to be avoided or dosage adjustments may be necessary; review drug interactions.
  - **Rocuronium Bromide Solution for injection; Adults**: 0.6 to 1 mg/kg IV bolus, followed by 8 to 12 mcg/kg/minute continuous IV infusion; titrate to patient’s twitch response. Usual dosage range: 4 to 16 mcg/kg/minute. Coadministration of certain drugs may need to be avoided or dosage adjustments may be necessary; review drug interactions.
COVID-19 critical care

- Nondrug and supportive care
  - Excellent supportive care is the only treatment to date that appears to be consistently helpful in COVID-19
  - WHO, NIH, and Surviving Sepsis Campaign provide specific guidance for oxygenation, ventilation, and fluid management in COVID-19
    - Patients with severe respiratory distress, obstructed or absent breathing, central cyanosis, shock, seizures, or coma require aggressive airway management (which may include intubation) and oxygen
      - Assess severity of respiratory distress using the PaO₂/FIO₂ ratio; some guidelines and protocols use this ratio to direct management of oxygenation and ventilation
      - Mild acute respiratory distress syndrome: 300 mm Hg or less, but greater than 200 mm Hg
      - Moderate acute respiratory distress syndrome: 200 mm Hg or less, but greater than 100 mm Hg
      - Severe acute respiratory distress syndrome: 100 mm Hg or less
    - Oxygenation and ventilation
      - Begin supplemental oxygen therapy when oxygen saturation falls below 90% to 92%
      - Nasal cannula at 5 L/minute or face mask with reservoir bag at 10 to 15 L/minute
      - Titrate to reach SpO₂ of 94% or more initially
      - Once stable, target SpO₂ of 90% or higher in nonpregnant adults; 92% or higher in pregnant patients
      - In most children the target SpO₂ is 90% or greater; for those who require urgent resuscitation (eg, those with apnea or obstructed breathing, severe respiratory distress, central cyanosis, shock, seizures, or coma), a target SpO₂ of 94% or higher is recommended
      - High-flow nasal oxygen or noninvasive ventilation has been used to achieve adequate oxygenation in some patients
      - High-flow nasal oxygen is recommended by Surviving Sepsis Campaign and NIH. For patients with COVID-19 who develop hypoxic respiratory failure despite conventional oxygen therapy, there is some evidence that it averts the need for intubation and mechanical ventilation. Noninvasive positive pressure ventilation may be used if high-flow nasal oxygen is not available
      - However, there is concern that these techniques may result in higher risk of aerosolization of the virus. Additionally, sudden deterioration may require emergent intubation, which is associated with more risk to both patient and provider. Therefore, some authorities reserve these options for settings in which airborne precautions can be taken and close monitoring provided
      - Mechanical ventilation may become necessary for patients in whom oxygenation targets cannot be met with less invasive measures or who cannot maintain the work of breathing (eg, PaO₂/FIO₂ ratio of less than 300 mm Hg). For patients with moderate to severe acute respiratory distress syndrome, prone positioning for 12 to 16 hours/day is recommended
        - Lateral decubitus position for pregnant women
      - Sedation with or without neuromuscular blockade may be necessary for comfort and optimal ventilation; Society of Critical Care Medicine offers guidance on appropriate agents (eg, propofol, dexmedetomidine) and monitoring; shortages are occurring and American Society of Health-System Pharmacists offers guidance on substitutions
      - If neuromuscular blockade (eg, rocuronium) is needed (eg, for ventilator dyssynchrony), Surviving Sepsis Campaign guideline suggests intermittent boluses rather than continuous infusion
      - Mechanical ventilation may be required for a prolonged period, necessitating tracheostomy
      - Extracorporeal membrane oxygenation has been used in severely ill patients, and it can be considered if resources and expertise are available
    - Fluid management
      - Overhydration should be avoided, because it may precipitate or exacerbate acute respiratory distress syndrome
      - An assessment of likely fluid responsiveness may be made by measuring the change in cardiac output (by echocardiography or transpulmonary thermodilution) on passive leg raise; an increase in cardiac output after 1 minute of passive leg raise has been shown to be a reliable predictor of response and helps to avoid overhydration in patients unlikely to respond
In patients with shock:
- Administration of crystalloids is recommended (preferably buffered/balanced; eg, Lactated Ringer solution); solutions such as hydroxyethyl starches, gelatins, dextrans, and albumin are not recommended according to Surviving Sepsis Campaign guideline on managing critically ill adults with COVID-19. WHO provides the following guidance:
  - Adults: administer 250 to 500 mL over the first 15 to 30 minutes; goal is mean arterial pressure of 60 to 65 mm Hg (if invasive pressure monitoring is available)
  - Children: 10 to 20 mL/kg bolus over the first 30 to 60 minutes
  - If there is no response to fluid bolus or if signs of fluid overload exist, discontinue or reduce fluid administration
  - For patients who respond to initial bolus and are without evidence of fluid overload, titrate continued fluid to achieve improvement in clinical signs (capillary refill, heart rate, tactile temperature of extremities, palpable pulses), urine output (0.5 mL/kg/hour in adults, 1 mL/kg/hour in children), and hemodynamic parameters (mean arterial pressure more than 65 mm Hg in adults)

Procedures
- Extracorporeal membrane oxygenation
  - General explanation
    - Heart-lung bypass is a technique in which blood is circulated from patient through bypass machine, where transmembrane exchange of oxygen and carbon dioxide occurs before blood is returned to patient; can also be used to support arterial blood pressure
  - Indication
    - Refractory hypoxemia with or without hemodynamic compromise despite standard supportive measures
    - May be helpful if resources and expertise are available
  - Contraindications
    - Neurologic impairment
    - Severe preexisting disease
  - Complications
    - Limb ischemia distal to vascular access catheters

Comorbidities
- Severe COVID-19 has been associated with chronic conditions such as diabetes, hypertension, and other cardiovascular conditions; existing published guidance on COVID-19 management does not address issues specific to these comorbidities
- Owing to the role of the ACE2 receptor in the pathogenesis of COVID-19, controversy has arisen over the positive or negative effects that ACE inhibitors and angiotensin receptor blockers may have on the disease. A joint statement by the American College of Cardiology, American Heart Association, and Heart Failure Society of America recommends that persons who are currently taking these medications for appropriate indications should continue to do so
- Several analyses of data from large numbers of patients with COVID-19 have shown no association between ACE inhibitors or angiotensin receptor blockers and either acquisition of COVID-19 or severity of infection

Special populations
- Standard critical care monitoring, including oxygen saturation and hemodynamic measures, is appropriate
- For patients receiving chloroquine or hydroxychloroquine, monitoring of QTc is recommended
  - Perform ECG at baseline, 2 to 3 hours after second dose of drug, and daily thereafter
  - If QTc increases by more than 60 milliseconds or absolute QTc is greater than 500 milliseconds (or greater than 530 to 550 milliseconds if QRS exceeds 120 milliseconds), reduce dose and (if applicable) discontinue azithromycin
- Patients who are undergoing a trial of high-flow oxygen or noninvasive ventilation require especially close attention pending sustained improvement or decision to intubate

COMPLICATIONS AND PROGNOSIS

COMPLICATIONS
- Among ICU patients, the following complications have been noted most frequently:
  - Acute respiratory distress syndrome (60% to 70%)
  - Shock (30%)
  - Myocardial injury (20% to 30%) and arrhythmias (44%)
  - Acute kidney injury (10% to 30%)
- Secondary bacterial and fungal infections and multiorgan failure have also been commonly cited; thrombotic events are being recognized with increasing frequency
COVID-19 critical care

PROGNOSIS

• Patients who require hospital admission often require prolonged inpatient stay (more than 20 days), although duration of stay may be inflated by need for isolation until documentation of sustained absence of fever and serial negative results on polymerase chain reaction test.6,32
  ○ Deconditioning may be profound
• Laboratory markers associated with mortality include high D-dimer levels, high C-reactive protein levels, and low lymphocyte counts.
• Reported mortality rates in critically ill patients are high (on the order of 40% or more).7,2

SCREENING AND PREVENTION

PREVENTION

• In the critical care setting, infection control strategies are essential to prevent infection of staff and other patients; this includes standard, contact, and (at least) droplet precautions.42
  ○ Patients should be placed in a single room, with the door closed, and ideally with structural and engineering safeguards against airborne transmission (eg, negative pressure, frequent air exchange); but, in the high-prevalence stages of the pandemic (with crowded hospitals), reserve negative pressure isolation rooms for the greatest needs (ie, aerosol-generating procedures; tuberculosis, measles, and varicella)
  ○ Source control should be applied whenever possible; this consists of a face mask or cloth covering for nonintubated patients and measures to reduce leakage around oxygen masks and from ventilator tubing
  ○ Limit transport of patient from the room (eg, for studies or procedures). Arrange for portable studies and procedures if feasible; during aerosol-generating procedures, limit number of workers in room to those necessary
  ○ Persons entering the room should wear gloves, gowns, eye protection, and surgical/procedural mask with adherence to hospital donning and doffing protocols, including aggressive hand hygiene. For aerosol-generating procedures, a respirator at least as effective as an N95 should be used in place of a surgical/procedural mask
  ○ Equipment used for patient care should be single-use (disposable) or should be disinfected between patients; WHO suggests using 70% ethyl alcohol
• Criteria for discontinuation of isolation precautions may vary depending on resources. In patients who have had symptomatic illness, precautions should be maintained until the following conditions are met:76
  ○ Test-based
    – Demonstration of negative results of molecular assays for SARS-CoV-2 RNA on nasopharyngeal swabs obtained at least 24 hours apart (a single specimen suffices for each test), and
    – Subjective and objective evidence of clinical improvement, including absence of fever without use of antipyretic medication
  ○ Symptom-based
    – Subjective and objective evidence of improvement in respiratory symptoms and absence of fever without use of antipyretic medication for 72 hours, and
    – At least 10 days since onset of symptoms

SYNOPSIS

KEY POINTS

• COVID-19 (coronavirus disease 2019) is respiratory tract infection due to a novel coronavirus, SARS-CoV-2 (initially called 2019-nCoV); as of March 11, 2020, extent of infection was declared pandemic by WHO.1
• About 5% of diagnosed cases require critical care to manage severe manifestations and complications.2 Among patients with COVID-19 who are critically ill, mortality rates of 39% to 72% are reported.3
• There is no specific antiviral therapy, although compassionate use and trial protocols for several agents are underway. At present, remdesivir appears most promising, based on preliminary reports of a large prospective randomized controlled trial;46 otherwise, treatment is largely supportive, consisting of supplemental oxygen and conservative fluid administration
• In patients with increasing hypoxemia, a cautious trial of high-flow oxygen or noninvasive ventilation may be undertaken. If significant improvement does not occur over a period of several hours, intubation and mechanical ventilation is indicated; optimal ventilatory strategy has not been clearly established, but most published recommendations are based on the ARDSNet protocol.9,66,7,52
• Pharmacologic support may be necessary in patients with shock whose hemodynamic parameters do not respond to fluids and oxygen; most guidelines favor norepinephrine as the initial agent for adults, and epinephrine in children.7,52,9
• The most common complications, after acute respiratory distress syndrome and shock, are myocardial and renal dysfunction. Thrombotic events, both venous and arterial, are increasingly recognized.7
• There is no vaccine available to prevent this infection; infection control measures are the mainstay of prevention (ie, standard, contact, and at least droplet precautions, with strict attention to proper donning and doffing of personal protective equipment)
URGENT ACTION
- Patients with respiratory distress require prompt administration of supplemental oxygen; patients with respiratory failure require intubation and mechanical ventilation
- Patients in shock require urgent fluid resuscitation and administration of empiric antimicrobial therapy to cover possible bacterial pathogens and/or influenza

PITFALLS
- Knowledge of this disease is incomplete and evolving; moreover, coronaviruses are known to mutate and recombine often, presenting an ongoing challenge to our understanding and to clinical management
